

Data Types

Data types in Java define the kind of data a variable can hold and the memory required to store it.

Java is a statically typed programming language, which means the data type of every variable is known at compile time. The compiler enforces type safety and prevents invalid assignments such as:

```
int x = "Hello"; // Compile-time error
```

1. Primitive Data Types (8 Types)

Primitive

—	byte	(1 byte)
—	short	(2 bytes)
—	int	(4 bytes)
—	long	(8 bytes)
—	float	(4 bytes)
—	double	(8 bytes)
—	char	(2 bytes)
—	boolean	(true/false)

► Numeric Types

- Integer Types: byte, short, int, long
- Floating Types: float, double

► Non-Numeric Types

- char
- boolean

Non-Primitive (Reference) Data Types

Non-Primitive

|

|— String

|— Array

|— Class

|— Interface

|— Object

Please refer to the DataType.java file in your code for all primitive data types handson and explanation.
